

Title and abstract

A case-control study of Exposure E among patients with Disease D. ^[1]

Methods

Cases were patients with a confirmed diagnosis of Disease D; controls were matched by age and sex at a 2:1 ratio. ^[6]

Conditional logistic regression was used to control for matching; missing exposure data were handled by multiple imputation. ^[12]

Results

Exposure E was present in 64% of cases and 31% of controls. ^[15]

Discussion

These findings support an association between Exposure E and Disease D. ^[20]
