

Title and abstract

A case-control study of Exposure E among patients with Disease D.

Methods

Cases were patients with a confirmed diagnosis of Disease D; controls were matched by age and sex at a 2:1 ratio.

Conditional logistic regression was used to control for matching; missing exposure data were handled by multiple imputation.

Results

Exposure E was present in 64% of cases and 31% of controls.

Discussion

These findings support an association between Exposure E and Disease D.
